Three black-box attacks, *one calibrated answer.*

TASK 01 · 2 MIN

Continuous dataset-usage estimation

Nine ResNet targets, three architectures. Reference bank, calibration line, nine continuous predictions.

TASK 02 · 2 MIN

PII extraction

Five prompt strategies benchmarked, direct memory probe wins. Per-PII ensemble closes the gaps.

TASK 03 · 2 MIN

LLM watermark detection

Shared black-box feature stack feeds two LogReg heads (softmax shape + green-list z-tests), fused by rank → CSV.

How much of a candidate dataset did each model train on?

Loss is a noisy proxy for membership. **Calibrate** it on attacker-trained models with known p, then **invert**.

STEP 01 Build the ruler — reference bank with *known* p

ResNet18	ResNet18	ResNet18	ResNet18	ResNet18
p = 0	p = ¼	p = ½	p = ¾	p = 1
LOSS 6.07	LOSS 4.55	LOSS 2.95	LOSS 1.53	LOSS 0.00

5 RESNET18 · TRAINED ON MIXED AT KNOWN PROPORTIONS · ≈ 1 GPU-HOUR

STEP 02 Feed the candidate dataset into the target → measure loss

CANDIDATE DATASET
N = 2000

INPUT →

?
BLACK-BOX TARGET

FORWARD PASS →

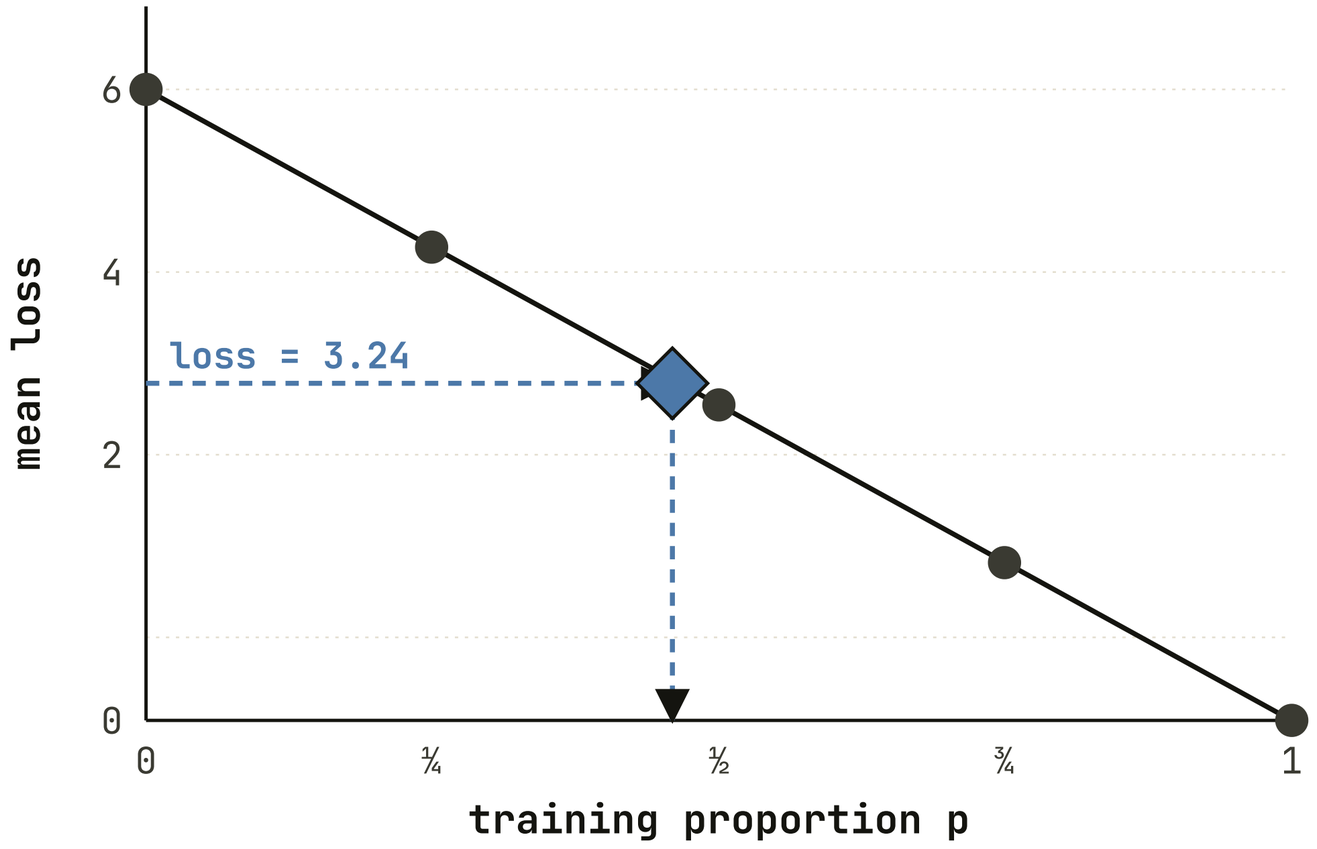
MEASURED MEAN LOSS
3.24

STEP 03 **Invert the line → recover p̂**

One linear fit, nine continuous predictions.

CALIBRATION · LOSS VS. TRAINING PROPORTION

`loss = -6.07·p + 6.06`



RECOVERED TRAINING PROPORTION **0.46**

Same recipe for all 9 targets — public benchmark MAE = 0.053.

REFERENCE **Tong et al. (DUCI, ICLR 2025)** report MAE = 0.0534 on ResNet-34 / CIFAR-100 with one reference model. We match the published single-reference benchmark on a harder **9-model, 3-architecture** setup.

Two prompt strategies, side by side.

Same model, same submission count — different aggregation rule.

PIPELINE

Two heads, one rank-fused score

Shared features → Head A · Head B → mean of ranks.

SHARED BLACK-BOX FEATURE STACK

540 LABELLED · 2250 TEST

- **surrogate LM** — token probs · ranks
- **binoculars** — GPT-2 / Pythia
- **OLMo-7B** — log-prob · PPL
- **OLMo-1B** — cross-scale
- **curvature** — DetectGPT-style
- **embeddings** — coherence

HEAD A

per-step softmax

OLMo-7B-Instruct

+ entropy · token rank

↓ logistic regression · L2

SCORE A

HEAD B

green-list z-tests

Kirchenbauer-style

+ tokenizer × γ variants

↓ logistic regression · L2

SCORE B

RANK FUSION

rank(A) + rank(B) → mean

FINAL CSV

SPECIALIST FEATURES

What each head adds on top of the shared stack

Distributional shape (A) vs. green-list statistics (B) — two complementary signatures.

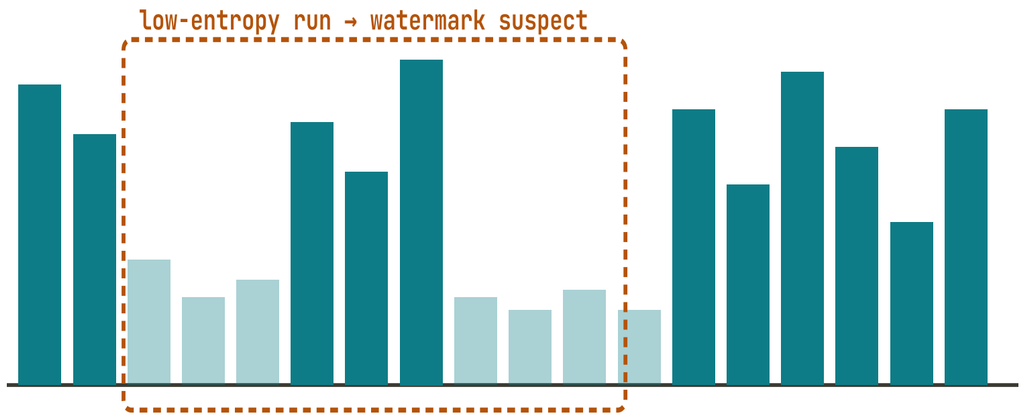
Same labels, same baseline columns, same six cross-model deltas. **Only one feature block differs**; that's where each head sees something the other can't.

HEAD A · OLMO-7B-INSTRUCT

Per-step full softmax — the shape of the distribution

not just averages: entropy, rank of realized token, bursts.

SOFTMAX ENTROPY ALONG THE SEQUENCE — LOW · HIGH



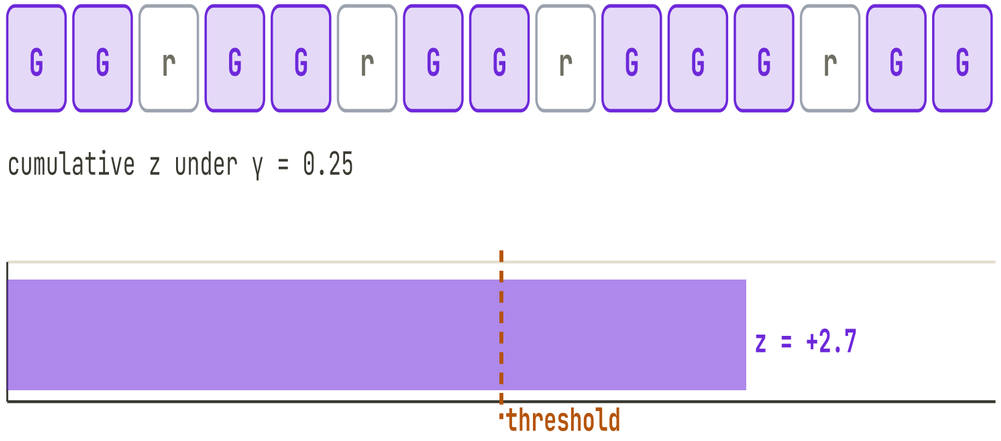
- entropy per step
- low-entropy run lengths
- rank of realized token
- tail-mass concentration

HEAD B · MULTI-CONFIG

Green-list z-tests — across many tokenizers + γ

cheap to add: no extra big-LM forward.

TOKEN POSITIONS · GREEN-LIST MEMBERSHIP — Z = +2.7



- multiple tokenizers
- context-seed schemes
- γ ratios scanned
- per-config + aggregate stats

TRADE-OFFS

What this two-head design buys — and where it leaks

Strengths and limitations of *this* rank-fused design.

STRENGTHS

✓ **Complementary signals.**
distributional shape (A) and list statistics (B) fail in different ways — their errors don't stack.

✓ **Rank merge aligned with the metric.**
TPR @ fixed FPR depends on order, not raw probability scale — mean of ranks is the natural fusion.

✓ **Modular heads.**
swap or retrain one block without touching the other.

LIMITATIONS

! **Equal weights in fusion.**
rank(A) and rank(B) averaged 50/50 — a learned blend is the obvious next move.

! **Heavily overlapping features.**
both heads share the wide vector — strong L2 keeps coefficients honest.

! **List-head schema risk.**
green-list z-tests sensitive to tokenizer / γ / seed mismatch.
